

Test-1

1. Explain about different Testing levels & its purpose?

There are four different testing levels they are,

- * Unit testing
- * Integration testing
- * System testing
- * User acceptance testing

1) Unit testing

The unit testing is also known as white box or Glass box testing.

It is done by the developers (their own created module)

It saves time and cost by finding early bugs.

ii) Integration testing

The integration testing is also called as API testing done in postman.

It is done by testers, after combining the unit tested modules to check whether they work correctly and no bugs are present.

iii) system testing

It is done by the testers after the whole software is integrated to verify it meets the specific requirements.

iv) User Acceptance testing

This is the final stage of testing done by the end-users or clients to verify the software is ready for deployment for real-world.

2. Explain about functional and non-functional testing. Give atleast 2 examples for each category.

functional testing

It is used to check whether the functionality of the software (feature) performs correctly without defect.

Ex:- Retesting

Once the bug is identified the developer fixes it then it was retested by the tester to check whether the bug is cleared.

Regression testing

It is used to verify that the bug fixes, new changes and system updates doesn't affect the existing functionalities.

* non-functional testing

The non-functional testing is used to check the metrics like performance, security and Accessibility. It is used to check the responsiveness.

Ex:-
load testing

The load testing is used to check the expected performance of the software by testing with expected traffic.

Accessibility testing

The developed software should be Accessible to every users like the disabled people.
